

STA 243: Homework 2

- Homework due in Canvas: 05/08/2019 at 11:59PM. Please follow the instructions provided in Canvas about homeworks, carefully.

1. **(5 Points)** This question is based on `StochasticOPT.pdf`. From the definition of Convex functions in Definition 2, show that the statement of Fact 5.0.1 (which is an alternate definition of convex functions that are one time differentiable) holds.
2. **(20 Points)** The origin of the dataset `housingprice.csv` we will use in this question is from the Coursera open course Machine Learning Foundations: A Case Study Approach by Prof. Carlos Guestrin and Prof. Emily Fox. Load the training data `train.data.csv` and testing data `test.data.csv`. We'll build our regression model on the training data and evaluate the model on the testing data.
 - (a) Build a linear model on the training data using `lm()` by regressing the housing price on these variables: `bedrooms`, `bathrooms`, `sqft_living`, and `sqft_lot`. What's the R^2 of the model on training data? What's the R^2 on testing data?
 - (b) The image below is Bill Gates' house. Load the file `fancyhouse.csv` to obtain the features of the house. Guess the price of his house using your linear model. Do you think the predicted price is reasonable?

Figure 1: Image fom Wikipedia Commons

- (c) Let's continue to improve the linear model we have. Instead of throwing only the raw data into the statistical model, we might want to use our intuition and domain expertise to extract more meaningful features from the raw data. This step is called feature engineering. Using meaningful features in the model is often crucial for successful data analysis. Add another variable by multiplying the number of bedrooms by the number of bathrooms, which describes the combined benefit of having more bedrooms and bathrooms. Add this variable to the linear model we have in Part (a). What's the R^2 of the new model on the training data and testing data respectively?
(Hint: You don't have to create a new column in the data frame. Try this trick in `lm(y ~ x1 + x2 + x1 * x2, data = your.data)`)
- (d) Perform all the things above without using the in-built function `lm()` in R, but by using **gradient descent algorithm** on the sample-based least-squares objective function, to estimate the OLS regression parameter vector. How does your result compare to the result from previous part ? Note that you have to set the tuning parameter appropriately for this method.

- (e) Perform all the things above now using `stochastic gradient descent` (with one sample in each iteration). How does your result compare to the result from previous parts ? Note: while running `stochastic gradient descent`, you can sample without replacement and when you run out of samples, just start over. Note that you have to set the tuning parameter appropriately for this method.
3. **(0 Points)** Understand the proof of Theorem 3.2 (in `StochasticOPT.pdf`) from the reference mentioned and replicate it
4. **(0 Points)** Prove Fact 6.1.1 in `StochasticOPT.pdf` and solve the recursion to obtain the final result of Theorem 6.1.
